ITT RAYONIER CLASS II INSPECTION

by Don Reif

Washington State Department of Ecology Environmental Investigations and Laboratory Services Compliance Monitoring Section Olympia, Washington 98504

October 1989

ABSTRACT

Ecology conducted a Class II inspection at the ITT Rayonier pulp mill at Hoquiam on May 23-25, 1988. The mill was meeting all effluent permit limits during the inspection although effluent quality was very poor. High effluent toxicity was observed in the Pacific oyster bioassay (EC₅₀ of 0.2% effluent). No specific cause of the toxicity was determined. Silver and copper exceeded EPA's water quality criteria. Other contaminants did not exceed criteria. Several factors combined to render near-field sediment analyses inconclusive. Recommendations were made in the areas of laboratory procedures, plant operation, and future sampling.

INTRODUCTION

A Class II inspection was conducted at ITT Rayonier in Hoquiam on May 23-25, 1988. Timing of the inspection coincided with a multi-agency study into low survival of Chehalis River coho salmon. The inspection was performed by Don Reif of Ecology's Environmental Investigations and Laboratory Services Program, Compliance Monitoring Section. Assistance was provided by Jerry Schaaf and Dennis Davies from ITT.

The inspection objectives were to:

- Collect effluent samples to check NPDES permit compliance.
- Characterize the wastewater to identify pollutants of concern.
- Perform a series of effluent and sediment bioassays to assess toxicity, and to collect data for continued development of Ecology's biomonitoring program.
- Perform a laboratory evaluation, including sample splits, for accuracy and adherence to accepted analytical protocols.
- Provide data to meet objectives of the Grays Harbor salmon study.

This report is one of two Class II inspection reports associated with the salmon study. The other was conducted at the Weyerhaeuser, Cosmopolis pulp mill (Hallinan, 1989). Results of the other aspects of this study will be published by the Department of Ecology (Johnson, in preparation) and the Department of Fisheries.

LOCATION AND DESCRIPTION

ITT Rayonier, Inc., Grays Harbor Division, is located in Hoquiam at Grays Harbor on the central Washington coast (Figure 1). The plant produces about 400 tons per day of paper grade bleached pulp. The majority of the pulp is processed at Grays Harbor Paper Company, adjoining the pulp mill.

ITT's on-site wastewater treatment plant treats an average of 20 MGD of process wastewaters generated by the pulp plant, Grays Harbor Paper Company, and the nearby ITT Rayonier vanillin plant. A schematic of the treatment system is shown in Figure 2. Pump stations at various mill locations collect the influent streams, consisting of spent sulfite liquor and occasionally hot caustic and/or vanillin black liquor. The influent undergoes primary treatment, with polymer addition to enhance the removal of wood fibers and other particulates. The primary effluent is treated in a complete-mix activated sludge lagoon. Nutrients, as phosphoric acid and ammonium phosphate, are added to allow proper biological growth. The activated sludge is then settled in three secondary clarifiers.

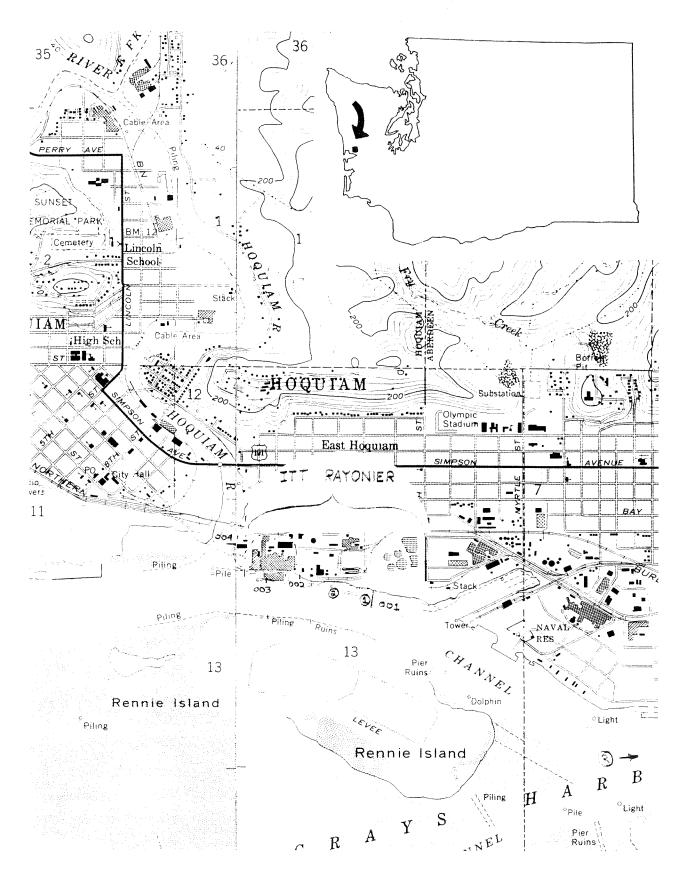

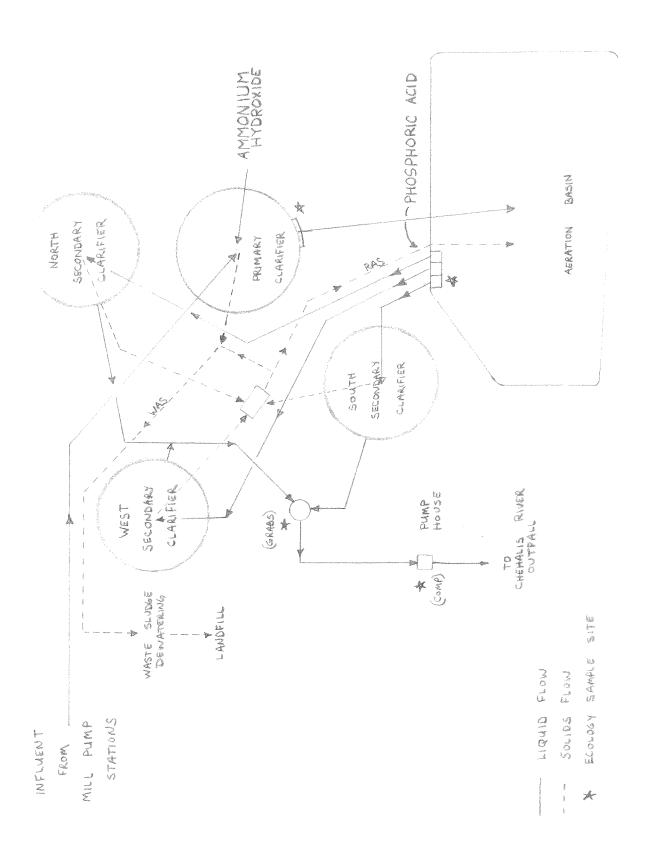

Figure 1. Mill location with treatment system, outfalls, and sediment sampling sites:

ITT Rayonier, Hoquiam Class II Inspection; May 23-25, 1988.

Process wastewater treatment system with sampling locations: ITT Rayonier, Hoquiam Class II Inspection; May 23-25, 1988. Figure 2.

Final effluent is discharged to the north channel of the Chehalis River in Grays Harbor estuary (outfall 001). Three other outfalls discharge nearby, carrying cooling water from chemical recovery and the powerhouse (002), old filter plant backwash and overflow water and paper mill cooling water (003), and new filter plant overflow and backwash water (004).

Waste activated sludge (excess activated sludge) has in the past been reintroduced to the final effluent before discharge, in amounts less than the daily permitted maximums for BOD and TSS. This practice did not occur during the inspection due to poorer-than-normal effluent quality (D. Davies, ITT, personal communication). Since a ruling by the Pollution Control Hearings Board (case #85-218, January 6, 1989), this method of sludge disposal is prohibited.

METHODS

The sampling schedule, including field analyses, is listed in Table 1. Sampling locations are shown in Figures 1 (sediment) and 2. Sample analysis was performed by Ecology's Manchester Laboratory and several contract labs. Analytical methods with references are summarized in Table 2.

A twenty-four hour effluent composite sample was collected at ITT's final effluent sampler building. Approximately 220 mL of sample were collected at 30-minute intervals. Effluent bioassay samples consisted of two-grab composites due to the large volume necessary. Grab samples were also taken of primary clarifier effluent, aeration basin effluent, and final effluent, as well as the other permitted discharges (Table 1). A sample of thickened sludge was collected from the sludge handling building.

Two sediment samples were collected off the outfall diffuser. However, the exact outfall line location was not positively identified due to a lack of available reference information. Therefore, the exact sampling locations with regard to the outfall is uncertain. The first was taken about 20 feet downstream of the outfall diffuser, and the second 300 feet downstream of #1. Cow Point, above Rennie Island, was used as a reference sample location.

Sediment toxicity was assessed with the marine amphipod *Rhepoxinius abronius*. Rainbow trout, *Daphnia pulex*, mysid shrimp, and oyster larvae bioassay tests were used to evaluate toxicity of the final effluent.

RESULTS

Flow

Flow through ITT's outfall #001 is measured with an inline venturi-type flow meter located before the outfall control house. Verification of meter accuracy was not possible. The outfall line is inaccessible except for the outfall control house, where flow control valves do not allow the use of an ultrasonic flow measuring device. Ecology's ability to verify flow rate is necessary to prove permit compliance. ITT should provide a safe and easily accessible flow sampling location.

		And a state of the

For the inspection period, a flow of 21.55 MGD was recorded by ITT's meter and is used in subsequent loading calculations.

General Conditions

An examination of general chemistry results in Table 3 reveals some noteworthy points. First, effluent total suspended solids (TSS) seem excessive for an activated sludge plant (120-320 mg/L). Supporting this statement further is the fact that final effluent TSS was higher than in the primary clarifier effluent. Also, total solids removal was very slight. COD removal was modest in the secondary system. A check of secondary clarifier surface overflow rate, weir overflow rate, and solids loading rate indicated all were well within design parameters for domestic activated sludge systems. Therefore, the poor effluent quality would not seem to be related to the system's design (see permit compliance section). During several visits to the treatment system, several draft tubes (the clarifiers' sludge removal system) appeared to be clogged and nonfunctional, which could contribute to high solids carryover into the effluent. High effluent solids may be related to the WTP's operation and maintenance rather than design limitations or wastewater characteristics.

Also visible from Table 3 is nutrient levels in the WTP. The locations of ammonia and phosphorus addition can be seen. Final effluent concentrations were low for both nutrients, which should be good for protection of the receiving water environment. It appears, however, that nitrification occurred in ITT's composite sample. Table 3 shows that most of the ammonia in ITT's effluent composite sample had been converted to nitrate and/or nitrite. Decreased alkalinity, another indicator of nitrification, also occurred. Nitrification was not seen in grab samples or Ecology's composite sample. Therefore, the nitrification probably occurred due to a buildup of nitrifying bacteria in the sampling lines and/or sample container. This could affect the BOD test. Regular monthly cleaning of ITT's composite sampler lines and containers with a dilute chlorine solution is recommended.

Permit Compliance

Table 4 compares results of Ecology's composite sample to NPDES permit limits for ITT's main outfall, #001. BOD and pH were well within permitted limits. The trout bioassay passed with no mortality at 65 percent effluent. Total suspended solids exceeded the daily average limit but were less than the daily maximum allowed. Also, one of two fecal coliform analyses exceeded the monthly average criteria. Fecal coliforms can be associated with TSS and turbidity. The higher coliform count was found at the higher turbidity and TSS concentration. Associated with these solids are conventional, organic, and potentially toxic substances as noted in the effluent and sludge analyses. For these reasons, ITT is urged to operate all three clarifiers at all times and to flush out and adjust the flow through the secondary clarifier draft tubes daily, as part of their normal operating procedure.

Priority Pollutant Scan/Organic Analyses

Summaries of priority pollutants and other target chemicals that were detected are in Table 5 (organics) and Table 6 (metals). Complete results of analyses are listed in the appendices. These tables are referred to in the following discussions.

B - parameter detected in field transfer blank. $\mbox{\ensuremath{\mathtt{^{+}}}}$ - parameter detected in laboratory blank.

Effluent Chemistry

Only a handful of organic compounds at relatively low concentrations was detected in ITT's effluent (Table 5). These included several phenols, a phthalate, several fatty acids, a guaiacol and a catechol. The highest concentration was chloroform at 320 ug/L, which is one-fourth (1240 ug/L) of EPA's quality criteria for chronic protection of freshwater organisms (EPA 1986a). No chlorinated pesticides, PCB's, organophosphorus pesticides, or herbicides were detected.

Concentrations of several metals exceeded EPA receiving water quality criteria for protection of aquatic life. These were chromium, copper, nickel, and silver. However, the effluent was analyzed for total metals which may overestimate concentrations bioavailable to aquatic life. EPA recommends criteria values be compared to total recoverable metals. With this possible overestimation and the amount of available dilution for the effluent, silver and copper are the only metals that might have a receiving water impact.

Effluent Bioassays

No acute toxicity was indicated by effluent bioassays (Table 7). However, a particularly high amount of chronic toxicity was found in the oyster larvae test (EC₅₀ of 0.2% effluent). The cause of this toxicity is not clear, although the oyster larvae test is known to be quite sensitive to pulp mill effluents (Hallinan 1989). Metals may have been a factor, since several exceeded EPA water quality criteria, especially silver and copper (Table 6). However, both the semivolatile and resin acid scans tentatively identified many organic compounds in the effluent (Appendix 10). No chlorinated compounds were identified. Information on the remainder was difficult to find and inconclusive.

Sediment Chemistry

Volatile organics, pesticides, and PCB's were not detected in the sediment samples (Appendices 1 and 4). However, several semi-volatiles (BNA's), including phthalates, polynuclear aromatic hydrocarbons (PNA's), 4-methylphenol, phenols, resin acids, fatty acids, and guaiacols were detected at low concentrations (Table 5). Metals (Table 8) were below AET values except for chromium and nickel, which exceeded the most restrictive of the proposed AET levels. Several dioxin and furan isomers were found at low concentrations (see Johnson, 1989, for more details). Concentrations of these organic compounds and metals were not appreciably higher than at the upstream control. However, two factors make comparisons difficult. First, Cow Point has been determined to be a poor control station, since it is probably within the zone of tidal influence from Gray's Harbors' pulp mills (Hallinan, 1989). Also, the samples collected may not be representative of ITT's diffusers' near-field sediments due to location uncertainties mentioned earlier.

Sediment Bioassays

Sediment toxicity was not exhibited by *Rhepoxinius* (Table 7). No significant differences in response were noted between the three field samples and the lab control, although mortality

Table 7. Bioassay Data Summary - ITT-Rayonier, Hoquiam Class II Inspection: May 23-25, 1988.

Bioassay	Results
<u>Effluent</u>	
Acute tests: Rainbow Trout	0% mortality @ 65% effluent.
Daphnia pulex	0% mortality @ 100% effluent.
Mysid Shrimp	$LC_{50} > 100\%(1)$.
Chronic test: Oyster larvae	EC_{50} of 0.2% effluent, based on larvae abnormality(2).
Sediment	Survival(3) Avoidance(4) % Reburial(5)
at ITT	18.8 +/- 1.3 0.3 +/- 0.5 98.9
below ITT	17.2 +/- 1.1 0.2 +/- 0.4 98.9
Field Control	18.6 +/- 1.1 0.1 +/- 0.3 98.9
Lab Control	18.8 +/- 1.6 0.7 +/- 1.1 100

^{1 -} LC_{50} = concentration lethal to 50% of the organisms(Ecology 1988).

^{2 -} EC_{50} = concentration causing the tested effect to 50% of the organisms (Ecology 1988).

^{3 -} Mean, based on twenty amphipods per replicate: five replicates per sample.

^{4 -} Number of amphipods on jar surface per day, out of twenty.

^{5 -} Number of amphipods able to rebury in clean sediment at end of test period.

1988 Lowest Apparent Effects Threshold Value

Sediments Criteria Report, August 1988, PTI Environmental Services, i.e. Highest Apparent Acute to Chronic Ratio No Observable Effects Concentration as reported in Contaminated

Effects Threshold value divided by 10. The SL is defined as no lower than mean reference area Puget Sound Dredged Disposal Analysis Screening Level (SL), ie, the 1986 Highest Apparent Effects Threshold Value, whichever is lower

(4)

- candidate AET's were compiled by Brett Betts of Ecology's Sediment Management Unit.

values and no higher than the 1986 lowest apparent effects threshold value

was somewhat higher in sample #2. Avoidance and reburial also were similar and unremarkable.

Sludge Chemistry

Sludge contaminant concentrations tended to be much higher than in the outfall sediments. Compounds detected in the sludge are summarized in Table 5. Several BNA's were found, including phenol, 4-methylphenol, and several PNA's. Phthalates, found in the sediments, were noticeably absent in the sludge. The sludge also contained concentrated resin acids and guaiacols as compared to the sediments. Most of the same dioxin/furan isomers found in the sludge were also present in the sediments.

Three herbicides - Diuron, Atrazine, and Butylate - were also detected. These compounds can provide general and/or specific vegetation control, depending on application rates (Meister, 1988). They are probably used for weed control around the plant and find their way to the treatment plant via the plant's stormwater collection system. The concentrations detected in the sludge (3, 0.2, and 0.5 parts per million for Diuron, Atrazine, and Butylate, respectively) are well below acute oral LD₅₀ concentrations for rats (3400, 1780, and 3500 parts per million, respectively). Other possible effects or concerns for sludge disposal, etc., are not known. These herbicides were not detected in the effluent composite sample or sediments.

Sludge metals are compared to criteria in Table 9. First, priority pollutant metals are compared to freshwater sediment criteria from the state of Wisconsin. From this analysis, ITT's sludge exceeded the criteria for cadmium and chromium. The data are also compared to the results of previous inspections of municipal sludges. ITT's sludge is well within 'normal' metals concentrations except for chromium, which was much higher than average, equaling the highest level observed in 34 samples. Chromium was also high compared to Weyerhaeuser, Cosmopolis results (296 vs. 6.9 mg/kg dry wt.). Finally, results of the metals extraction procedure toxicity test (EP TOX) are compared to Ecology's criteria for designation as a dangerous waste. No metals exceeded these criteria.

Laboratory Review/Split Samples Comparison

A review of ITT's lab procedures revealed that a confusing mixture of references is used. These include Standard Methods (APHA, 1975), Ecology's BOD procedure (Ecology, 1977), and ITT's custom modifications of both (Davies, 1981). All three of these references are outdated, which contribute to several departures from commonly accepted protocols. Most notable was ITT's procedure for the seed BOD determination. Results of seeded dilution water blanks (a QA/QC check) are mistakenly substituted for the actual BOD of the seed, which is not determined. This subject was addressed in an earlier memo (Reif, 1988). To assure correct analytical analyses and to maintain equity within Ecology's regulated industrial dischargers, it is recommended that ITT follow the latest edition of Standard Methods (1985) for all NPDES test protocols.

Comparison of lab results from split samples are listed in Table 10. Comparisons were acceptable for BOD and pH. TSS values did not compare well on four of seven samples. On

^{* -} from Standard Methods (APHA, 1985)

all splits except the aeration basin sample, ITT's figure was less than Ecology's. Also, the fecal coliform split did not compare well (21,000 vs 1200), as had the fecal split from the previous inspection (too numerous to count vs. 1200- Kjosness, 1987). Therefore, further splits of fecal coliform and TSS samples with ITT are recommended.

CONCLUSIONS AND RECOMMENDATIONS

- Although the mill was not in technical violation of its NPDES discharge permit during the inspection, the effluent daily average limit for suspended solids was exceeded, as was the monthly average fecal coliform limit on one of two samples. Effluent quality was poorer than should be expected. The poor quality effluent did not seem related to design restrictions. ITT is urged to operate all final clarifiers simultaneously and to flush out and adjust clarifier return sludge drawoff tubes daily. In addition, an access point to allow independent verification of flow rate for the main outfall is needed.
- Effluent pollutants found were chloroform at 320 ug/L and several other organics at very low concentrations. No contaminants exceeded established criteria. Silver and copper exceeded EPA's water quality criteria for chronic protection of aquatic life by nearly an order of magnitude.
- The Pacific oyster bioassay indicated a high level of chronic effluent toxicity. Future chronic toxicity testing should include the Pacific oyster larvae bioassay. Few adverse acute effects were noted. No effluent mutagenic activity was found in the Ames test.
- Sediment samples showed no significant acute toxicity. Organic and metal contaminants were not significantly elevated with respect to the upstream control sediment, including dioxin. Detailed location information is needed on ITT's outfall to allow proper sediment collection in the future.
- Waste activated sludge was found to contain many organic compounds, including phenols, PNA's, resin acids and guaiacols, dioxin and furan isomers, and three herbicides. Some metals exceeded various criteria, especially chromium.
- Sample splits for permit parameters did not compare well for suspended solids and fecal coliforms. Further splits of fecal coliform and TSS samples are recommended. Monthly cleaning or replacement of compositor sampling lines should eliminate sample nitrification.
- The seed BOD procedure is not used correctly. Use of the latest edition of Standard Methods is recommended for lab protocols to avoid confusion, assure highest analytical accuracy, and maintain equity between industrial dischargers.

U - indicates compound was analyzed for but not detected at the given detection limit.

NA- analyte was not analyzed for.

J - indicates an estimated value when result is less than specified detection limit.

 $[\]ensuremath{\mathtt{B}}$ - analyte was found in the blank as well as the sample, indicating possible/probable blank contamination.

 $[\]ensuremath{\mathtt{R}}$ - indicates analysis was attempted but was unsuccessful. Analyte may or may not be present.

Appendix 6. Metals Results: ITT Rayonier Class II Inspection - May 23-25, 1988

		-	Sediment (mg/kg dw)				
Metal	Effluent (ug/L)	Sludge (mg/kg dry wt)	at ITT	below ITT	Cow Point
